Project name:
XXXXX

Application type: **booking web application**

Test period: 1 day, 9.00 - 19.00, DD.MM.YYYY

QA team: XXX (A, B, C, D)

QA team mentors: E, F

Executive Summary

Stakeholders

- The high-profile client in the hospitality industry as the key stakeholder
- Users who will interact with the booking system during real reservation flow
- Developer Team
- QA team

Project context

The high-profile client in the hospitality industry as the key stakeholder requested the development of booking application for a newly established accommodation facility located in the English Woodlands. Due to the start of the hunting season and the expected influx of the international visitors, the application must be released within the strict 14-day deadline. The development team successfully delivered the first functional version go the application within 4 days, enabling the QA team to begin immediate validation.
https://…

Testing objective

The purpose of this testing effort is to ensure that the application meets essential functional, usability, and quality standards before being handed over the client. Given the high financial impact and reputational risks associated with potential issues at launch, thorough and efficient testing is critical. The testing team not only verifies technical correctness but also acts as representatives of actual users who will interact with the booking system during real reservation flow.

Testing results

No blocking defects were identified during testing. However, several critical issues were found what affect core functionality, specifically room reservation process, payment processing, and API structure. These defects have a significant impact on the system's ability to support essential booking operations and must be resolved prior to release. Additional usability and visual design problems were also observed, which negatively influence the overall user experience and may reduce user confidence in the system.

This report summarizes the testing activities performed, defects identified, and key recommendation required to support a stable and reliable release of the application, thereby helping the client secure a successful opening of their high-end accommodation during peak season.

Test approach and organization

Testing strategy objectives

- Quickly familiarize the team with the application through short ad-hock sessions.
- Identify critical user flows and verify them through classic requirement analysis and focused test-case creation.
- Use exploratory testing to uncover defects efficiently due time pressure.
- Validate API endpoints supporting the critical functionality to ensure accurate responses.
- Maximize defect detection within time constraints.

Risks&limitations

- Very limited time restricted full coverage.
- Only partial requirement analysis was possible .
- Potential for undiscovered defects in less critical and non-explored areas.

Team members responsibilities

The testing team consisted of 4 manual testers woking collaboratively. Due to the highly time-boxed nature of the task, the team applied elements of rapid and extreme testing, focusing on speed, adaptability, and continuous reassessment of priorities and responsibilities:

- focus on highest-risk areas;
- continuous collaboration;

- high adaptability;
- tester autonomy;
- immediate defect reporting
- minimal documentation.

Testing methods

- Ad-hoc testing
- Requirements analysis and test case design
- Nonfunctional testing
- Exploratory testing
- API testing

Testing tools

- Web browsers: Google Chrome, Mozilla, Brave, Safari;
- Operation systems: Windows, Linux, MacOS;
- Developers tools;
- Test management tools: JIRA, Zephyr;
- Postman.

Testing process overview

Testing activities were executed in two sprints. Sprint 1 focused on initial ad-hoc testing and critical user stories. Sprint 2 focused on exploratory testing and API validation.

Sprint 1

Timeframe: 9.15 - 13.30

1. Ad-hoc testing (initial familiarization)

In the morning, each team member performed quick unstructured ad-hoc testing to gain an initial understanding of the application and identify obvious issues, using a fresh perspective to better

reflect the real user experience. All tests were executed across different operating systems and web browsers to maximize coverage and defect environment-specific defects.

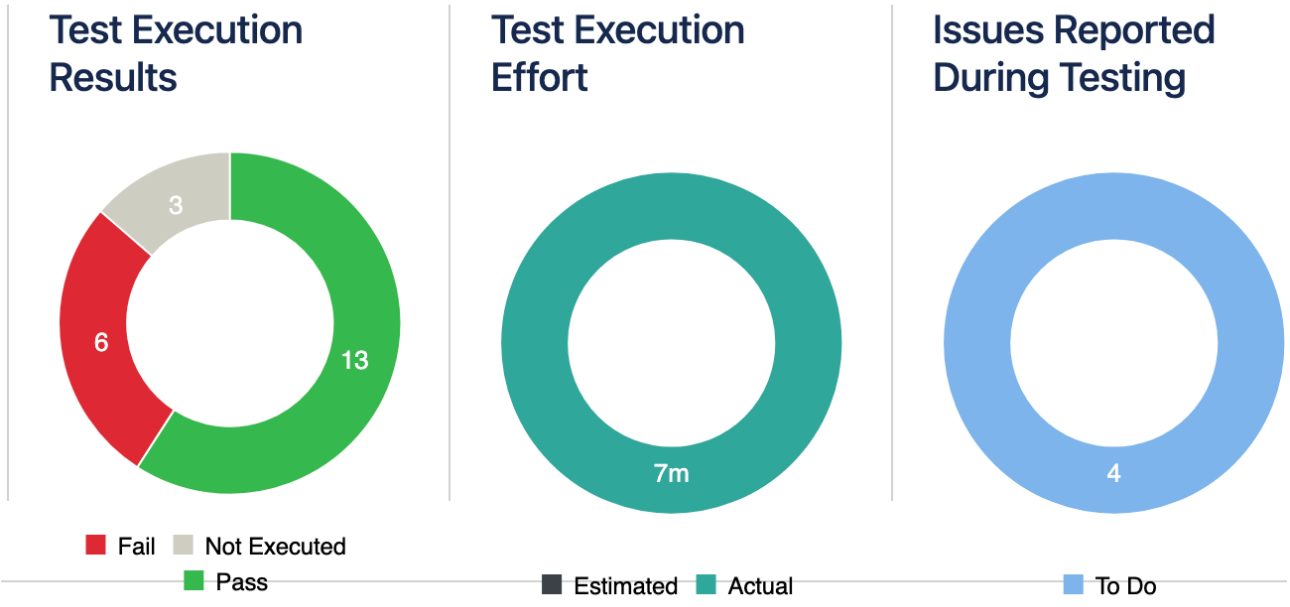
- Timeframe 9.15 - 10.15
- Conducted short, unstructured sessions to explore interface layout, navigation, and overall functionality
- Utilized benefits of “fresh eyes” to identify early usability issues and obvious blockers

2. Critical path identification

- Timeframe 10.15 - 10.45
- Mapped the user flows required for the application to function properly
- The critical path of the application includes selecting a room, completing the reservation, and processing the payment, as these steps are essential for end-to-end functionality.

3. Requirements analysis, test case design and execution

- Timeframe 10.45 - 13.30
- Performed targeted requirements analysis for 6 highest level and 1 medium level. .priority user stories from Nonfunctional requirements, Reservation process and Checkout epics.
- Test Plan “SPRINT1” includes 5 Test Cycles with 21 of high-priority test cases focusing on functional correctness of main risks
- Executed all designed test cases to validate core functionality.



Sprint 2

Timeframe: 14.00 - 19.00

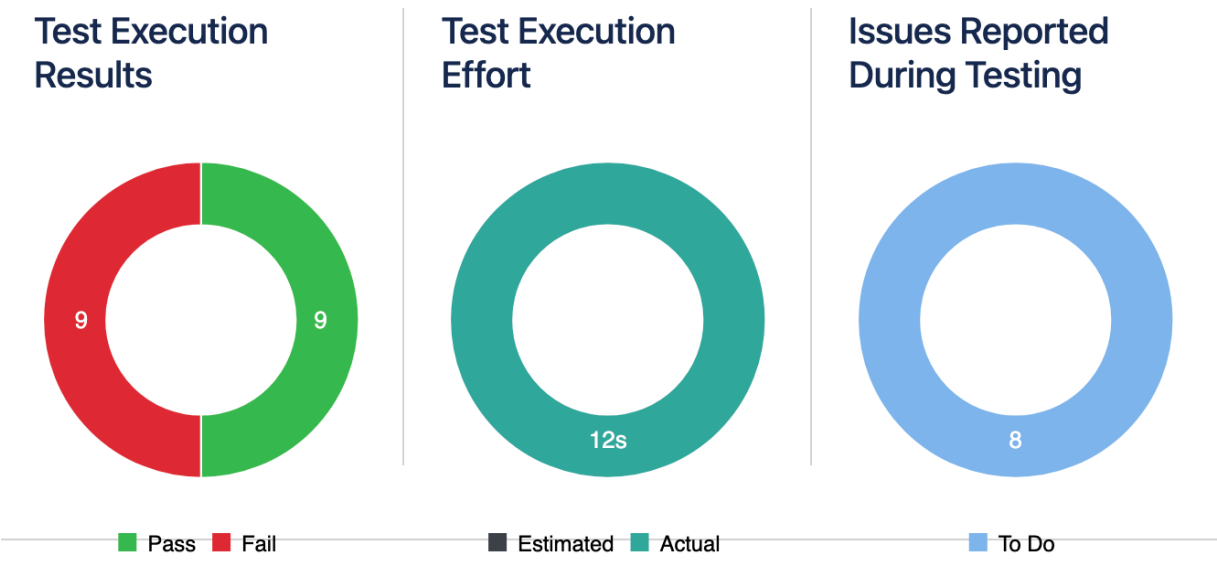
For the Sprint 2 we changed our strategy and divided the roles. A started to write test cases, D and B started to report bugs and C was focused on API. At about 16.00 Sprint 2 was extended , and Sprint 3 was subsequently cancelled.

1. **Exploratory testing**

- Performed charter-based exploratory sessions using user stories as guidance;
- Focused on uncovering defects and edge cases within the critical functionality;
- Reported issues in real time during execution;
- Total issues: 23

2. **Requirements analysis, test case design and execution**

- Performed requirements analysis for Footer section.
- Test Plan “SPRINT2” includes 2 Test Cycles with 18 test cases, one of them for API testing.
- Executed all designed test cases to validate core functionality.



3. **API Testing**

- API documentation https://…
- Performed API documentation analisys
- Validated key API endpoints

- Checked response correctness, status code and data validation.
- Total endpoints: 4; total requests: 14; total tests: 33; Pass: 29; Fail: 4.
- Postman collection : https://www.postman.com/…

Defect Overview

No blocking defects were identified during testing. However , several critical issues were found what affect core functionality, specifically room reservation process, payment processing, and API structure. These defects have a significant impact on the system's ability to support essential booking operations and must be resolved prior to release. Additional usability and visual design problems were also observed, which negatively influence the overall user experience and may reduce user confidence in the system.

API testing:

Documentation analysis result:

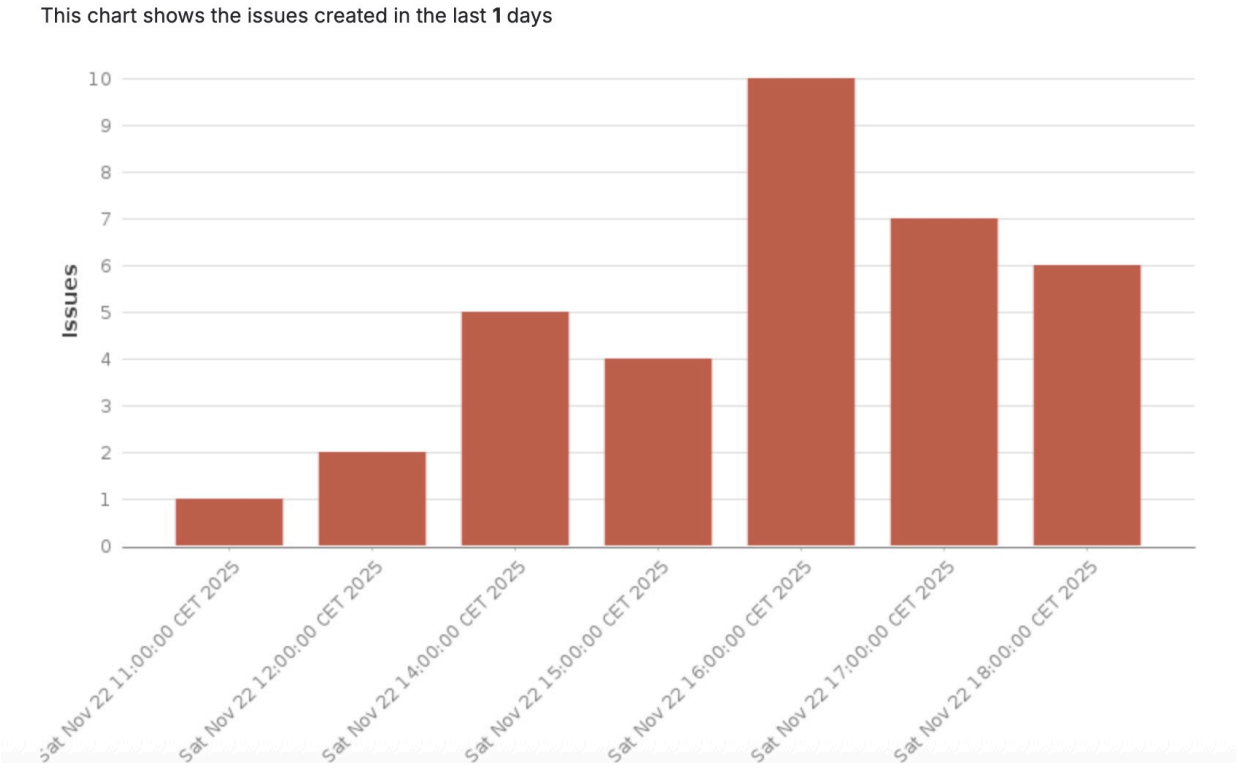
> Analysis of API documentation revealed that it does not establish a clear relationship between API requests and business processes, which makes the functional purpose of the endpoints insufficiently defined and increases the risk of incorrect implementation.

Test result:

DATBP253H-XX	API Data in response isn't 'data-time' format	=
DATBP253H-XX	API ID is requested twice in POST request	=
DATBP253H-XX	API bug in documentation	=

Ad-hoc testing, UI/UX issues, Improvements

- The “Location” and “Hotel” fields are present in the search section, even though the site represents a single hotel. Users may find these fields confusing or unnecessary.
- The language switcher is currently located in the footer, which is not where users typically expect to find it. This placement may reduce discoverability and hinder quick changes.
- During the booking process, users are unable to see the number of available rooms, which reduces transparency and may cause uncertainty when selecting room options. This issue affects both the Home page and the available rooms list page.



Testing process conclusion: Despite time and resource constraints, the team was able to validate critical functionality and uncover key defects using a combination of exploratory and priority testing.

The strategy of maximizing exploratory testing proved efficient and cost-effective under the time-boxed condition.

Recommendation

Based on current testing results, the system cannot be considered ready for release. Several high-severity defects directly impact essential booking and payment workflows, including reservation handling, payment execution and key API operations, preventing the platform from functioning as intended in real user scenarios. The issues must be addressed and verified before moving forward with deployment to ensure a rebate and secure user experience.

In the upcoming days It is recommended that the development team prioritize fixing the critical-path defects to restore end-to-end operability. At the same time the QA team should prepare a comprehensive set of test cases for full regression testing to ensure that resent fixes do not introduce new issues and that all major user workflows remain stable.

We also recommend:

- Clarifying the API's targeting audience (internal vs. external use) and formalizing a clear structural and functional model for all endpoints to ensure proper alignment with business processes and integration requirements.
- Displaying the number of available rooms for each room type to improve transparency, support informed booking decisions, and improve overall user experience.
- Removing the "location" and "hotel" fields from the Search form to simplify the interface and reduce user confusion.
- Moving the language switcher to the top-right corner of the page, aligning with common user expectations and improving overall navigation clarity.
